In all ultrasound-guided paravertebral block techniques, an indication of correct needle tip placement is the anterior displacement of the parietal pleura when the solution of local anaesthetic is being injected. Hydrolocation with saline can be used to help with needle tip position; this is particularly useful when the anatomy on

It can be performed at the Cervical, Thoracic or Lumbar level; however only the Thoracic Paravertebral block will be discussed here. Thoracic paravertebral block confers several advantages over epidural block: Comparable pain relief with reduced side effects. Better pulmonary function and fewer pulmonary complications; Contraindications to thoracic epidural block do not preclude thoracic paravertebral block e.g. systemic sepsis, deranged coagulation; Indications

Thoracic Paravertebral Block. Thoracic paravertebral block is the technique by which local anaesthetic is injected in wedge shaped paravertebral space alongside of the vertebral body called the thoracic paravertebral space (TPVS). This provides unilateral somatic and sympathetic blockade at selective segmental regions.

Thoracic Paravertebral Block - Nerve Blocks
Thoracic paravertebral block (TPVB) is the technique of injecting local anesthetic alongside the thoracic vertebra close to where the spinal nerves emerge from the intervertebral foramen. This produces unilateral, segmental, somatic, and sympathetic nerve blockade, which is effective for anesthesia and in treating acute and chronic pain of unilateral origin from the chest and abdomen.

Recently, there has been remarkable changes in the concept of thoracic paravertebral block (TPVB), and several indirect TPVB approaches have been described 1; erector spinae plane block (ESPB) is a representative indirect TPVB method, reported by Forero et al 2 in 2016. Most indirect TPVBs, including ESPB, are interfascial plane blocks.
